A Generalized FDTD Method with Absorbing Boundary
Condition for Solving a Time-Dependent Linear
Schrödinger Equation

ABSTRACT
The Finite-Difference Time-Domain (FDTD) method is a well-known technique for the analysis of quantum devices. It solves a discretized Schrödinger equation in an iterative process. However, the method provides only a second-order accurate numerical solution and requires that the spatial grid size and time step should satisfy a very restricted condition in order to prevent the numerical solution from diverging. In this article, we present a generalized FDTD method with absorbing boundary condition for solving the one-dimensional (1D) time-dependent Schrödinger equation and obtain a more relaxed condition for stability. The generalized FDTD scheme is tested by simulating a particle moving in free space and then hitting an energy potential. Numerical results coincide with those obtained based on the theoretical analysis.

Keywords: Schrödinger Equation; Absorbing Boundary; FDTD Method; Stability

1. Introduction
The 1D time-dependent linear Schrödinger equation, which is the basis of quantum mechanics [1,2], can be expressed as follows [3,4]:

\[
\frac{\partial \psi(x,t)}{\partial t} = i \frac{\hbar}{2m} \frac{\partial^2 \psi(x,t)}{\partial x^2} - i \frac{V(x,t)}{\hbar} \psi(x,t),
\]

(1)

where \( \hbar \) is Planck’s constant, \( V \) is the potential (J), \( \psi(x,t) \) is a complex number, and \( i = \sqrt{-1} \). The product of \( \psi(x,t) \) with its complex conjugate, \( \psi(x,t) \cdot \overline{\psi(x,t)} \), indicates the probability of a particle being at spatial location \( x \) at time \( t \).

It can be easily seen that the classic explicit two-level in time finite difference scheme, i.e.,

\[
\psi^{n+1}(k) - \psi^n(k) = i \frac{\hbar}{2m\Delta x^2} \psi^n(k) - i \frac{V}{\hbar} \psi^n(k),
\]

(2)
is unconditionally unstable, where \( \psi^n(k) \) is the approximation of \( \psi(k\Delta x, n\Delta t) \). Here, \( \Delta x \) and \( \Delta t \) are the spatial grid size and time step, respectively, \( k \in \mathbb{Z} \) that denotes the set of all positive and negative integers, and \( \Delta^2 \) is a second-order central difference operator such that

\[
\Delta^2 \psi^n(k) = \psi^n(k+1) - 2\psi^n(k) + \psi^n(k-1).
\]

Thus, there are many numerical schemes developed for solving linear Schrödinger equations [1-33]. In particular, Sullivan [3] and Visscher [4] applied the finite-difference time-domain (FDTD) method, which is often employed in simulations of electromagnetic fields, to solve the above Schrödinger equation. The application of FDTD technique for the analysis of quantum devices is often called the FDTD-Q scheme, which can be described as follows [3].

The variable \( \psi(x,t) \) is first split into its real and imaginary components in order to avoid using complex numbers:

\[
\psi(x,t) = \psi_{\text{real}}(x,t) + i\psi_{\text{imag}}(x,t).
\]

(4)

Inserting Equation (4) into Equation (1) and then separating the real and imaginary parts result in the following coupled set of equations:

\[
\frac{\partial \psi_{\text{real}}(x,t)}{\partial t} = -\frac{\hbar}{2m} \frac{\partial^2 \psi_{\text{imag}}(x,t)}{\partial x^2} + \frac{V(x,t)}{\hbar} \psi_{\text{imag}}(x,t),
\]

(5)

and

\[
\frac{\partial \psi_{\text{imag}}(x,t)}{\partial t} = \frac{\hbar}{2m} \frac{\partial^2 \psi_{\text{real}}(x,t)}{\partial x^2} - \frac{V(x,t)}{\hbar} \psi_{\text{real}}(x,t).
\]

(6)
schemes as follows:

\[
\psi_{\text{real}}^{n+1}(k) - \psi_{\text{real}}^n(k) \Delta t = -\frac{h}{2m(\Delta x)^2} \delta_x^2 \psi_{\text{imag}}^n(k) + \frac{1}{h} V(k) \psi_{\text{imag}}^n(k),
\]

(7)

and

\[
\psi_{\text{imag}}^{n+1/2}(k) - \psi_{\text{imag}}^{n-1/2}(k) = \frac{h}{2m(\Delta x)^2} \delta_x^2 \psi_{\text{real}}^n(k) - \frac{1}{h} V(k) \psi_{\text{real}}^n(k).
\]

(8)

Here, we assume that \( V \) is dependent only on \( x \) for simplicity. The computation of the above FDTD-Q scheme is very simple and straightforward because one may obtain \( \psi_{\text{real}}^{n+1}(k) \) from Equation (7) and then \( \psi_{\text{imag}}^{n+1/2}(k) \) from Equation (8). Previously, the second author analyzed the stability of the FDTD-Q scheme using the discrete energy method and obtained a condition for determining the time step, \( \Delta t \), so that the scheme is stable as follows [13]:

\[
\frac{h}{m} \cdot \frac{\Delta t}{\Delta x^2} + \frac{\Delta t}{2h} \max |V| \leq c < 1,
\]

(9)

where \( c \) is a constant. It should be pointed out that Soriano et al. [27] and Visscher [4] also used the eigenvalue method to analyze the stability of the FDTD-Q scheme and obtained a very similar condition of

\[
\frac{h}{m} \cdot \frac{\Delta t}{\Delta x^2} + \frac{\Delta t}{2h} \max |V| \leq 1.
\]

However, as pointed out in [13], even if the condition \( \frac{h}{m} \cdot \frac{\Delta t}{\Delta x^2} + \frac{\Delta t}{2h} \max |V| = 1 \) is chosen, the numerical solution is still divergent. Equation (9) indicates that the condition must be less than 1 but not close to 1.

The motivation of this study is to apply the idea of the FDTD method to develop a generalized FDTD method with absorbing boundary condition for solving the linear Schrödinger equation, so that a more relaxed condition for stability may be obtained.

2. Generalized FDTD Method

To develop a generalized FDTD scheme, we assume that \( \psi_{\text{real}}(x,t) \) and \( \psi_{\text{imag}}(x,t) \) are sufficiently smooth functions which vanish for sufficiently large \( |x| \) and the potential \( V \) is dependent only on \( x \). We first rewrite Equations (5) and (6) as

\[
\frac{\partial \psi_{\text{real}}(x,t)}{\partial t} = \left(-\frac{h}{2m} A + \frac{V}{h}\right) \psi_{\text{imag}}(x,t),
\]

(10)

\[
\frac{\partial \psi_{\text{imag}}(x,t)}{\partial t} = \left(-\frac{h}{2m} A - \frac{V}{h}\right) \psi_{\text{real}}(x,t),
\]

(11)

where \( A = \frac{\partial^2}{\partial x^2} \) and employ the Taylor series method to expand \( \psi_{\text{real}}(x,t_n) \) and \( \psi_{\text{imag}}(x,t_{n+1/2}) \) at \( t = t_{n-1/2} = (n-1/2) \Delta t \) as follows:

\[
\psi_{\text{real}}(x,t_n) = \psi_{\text{real}}(x,t_{n+1/2}) + 2 \sum_{p=0}^{p+1} \left(\frac{\Delta t}{2}\right)^{2p+1} \frac{1}{(2p+1)!} \frac{\partial^{2p+1} \psi_{\text{real}}(x,t_{n+1/2})}{\partial t^{2p+1}}.
\]

(12)

We then evaluate those derivatives in Equation (12) by using Equations (10) and (11) repeatedly:

\[
\frac{\partial \psi_{\text{real}}(x,t_{n+1/2})}{\partial t} = -\left(\frac{h}{2m} A - \frac{V}{h}\right) \psi_{\text{imag}}(x,t_{n+1/2}),
\]

(13a)

\[
\frac{\partial^2 \psi_{\text{real}}(x,t_{n+1/2})}{\partial t^2} = \left(-\frac{h}{2m} A - \frac{V}{h}\right)^2 \psi_{\text{imag}}(x,t_{n+1/2})
\]

(13b)

\[
\frac{\partial^3 \psi_{\text{real}}(x,t_{n+1/2})}{\partial t^3} = \left(-\frac{h}{2m} A - \frac{V}{h}\right)^3 \psi_{\text{imag}}(x,t_{n+1/2}),
\]

(13c)

and so on. Substituting Equation (13) into Equation (12) gives

\[
\psi_{\text{real}}(x,t_{n+1}) = \psi_{\text{real}}(x,t_{n+1/2}) + 2 \sum_{p=0}^{N} \left(\frac{\Delta t}{2}\right)^{2p+1} \left(-\frac{h}{2m} A - \frac{V}{h}\right)^{2p+1} \psi_{\text{imag}}(x,t_{n+1/2}) + O\left(\Delta t^{2N+3}\right).
\]

(14)

Similarly, we employ the Taylor series method to expand \( \psi_{\text{imag}}(x,t_{n+1/2}) \) and \( \psi_{\text{imag}}(x,t_{n+1/2}) \) at \( t = t_n = n\Delta t \) as follows:

\[
\psi_{\text{imag}}(x,t_{n+1/2}) = \psi_{\text{imag}}(x,t_{n-1/2}) + 2 \sum_{p=0}^{p+1} \left(\frac{\Delta t}{2}\right)^{2p+1} \frac{1}{(2p+1)!} \frac{\partial^{2p+1} \psi_{\text{imag}}(x,t_{n+1/2})}{\partial t^{2p+1}}.
\]

(15)

Again, using Equations (10) and (11) repeatedly to evaluate those derivatives in Equation (15), we obtain...
higher-order accurate approximations for

gives

t the time-dependent linear Schrödinger equation as follows:

\[
\frac{\partial \psi_{\text{imag}}(x,t_n)}{\partial t} = \left( \frac{h}{2m} A - \frac{V}{h} \right) \psi_{\text{real}}(x,t_n),
\]

(16a)

\[
\frac{\partial^3 \psi_{\text{imag}}(x,t_n)}{\partial t^3} = \left( \frac{h}{2m} A - \frac{V}{h} \right) \frac{\partial^2 \psi_{\text{real}}(x,t_n)}{\partial t^2}
\]

(16b)

\[
\frac{\partial^3 \psi_{\text{imag}}(x,t_n)}{\partial t^3} = -\left( \frac{h}{2m} A - V \right)^3 \psi_{\text{real}}(x,t_n),
\]

(16c)

and so on. Substituting Equation (16) into Equation (15) gives

\[
\psi_{\text{imag}}(x,t_{n+1/2}) = \psi_{\text{imag}}(x,t_{n-1/2}) + 2 \sum_{p=0}^{\infty} \left( \frac{\Delta t}{2} \right)^{2p+1} \left( -1 \right)^p \left( \frac{h}{2m} A - \frac{V}{h} \right)^{2p+1} \psi_{\text{real}}^{n-1/2}(x,t_n) + O\left( \Delta t^{2N+3} \right).
\]

(17)

Thus, if \( A \psi_{\text{imag}}(k\Delta x,t_{n+1/2}) \) and \( A \psi_{\text{real}}(k\Delta x,t_n) \) are approximated using some accurate finite differences, one may obtain a generalized FDTD scheme for solving the time-dependent linear Schrödinger equation as follows:

\[
\psi_{\text{imag}}^{n+1/2}(k) = \psi_{\text{imag}}^{n-1/2}(k) + 2 \sum_{p=0}^{\infty} \left( \frac{\Delta \lambda}{2} \right)^{2p+1} \left( -1 \right)^p \left( \frac{h}{2m} A - \frac{V}{h} \right)^{2p+1} \psi_{\text{real}}^{n-1/2}(x,t_n),
\]

(18a)

\[
\psi_{\text{imag}}^{n+1/2}(k) = \psi_{\text{imag}}^{n-1/2}(k)
\]

(18b)

It should be pointed out that in Equation (18a) \( \psi_{\text{imag}}^{n+1/2}(k) \) may be approximated by a higher-order accurate Lagrange polynomial or some other higher-order accurate approximations. Once \( \psi_{\text{real}}^{n}(k) \) is obtained from Equation (18a), one may construct a similar higher-order accurate Lagrange polynomial or some other higher-order accurate approximations for \( \psi_{\text{imag}}^{n}(x,t_n) \) and then substitute it into Equation (18b) to obtain \( \psi_{\text{imag}}^{n+1/2}(k) \). Here, for simplicity, we limit ourselves to using finite difference approximations for the Laplace operator \( A \). Furthermore, it can be seen from the above derivations that Equation (18) can be readily generalized to the multi-dimensional cases. For the case where the potential \( V \) is dependent on both temporal and spatial variables, the derivations are similar to those in Equation (16) except that the product rule of derivative with respect to \( t \) should be used.

3. Stability

In order to prevent the numerical solution from diverging, we need to analyze the stability of the generalized FDTD method in Equation (18). Here, we consider that the Laplace operator \( A \) is only approximated by either a second-order central difference operator \( \frac{1}{\Delta x^2} \delta^2_x \) or a fourth-order central difference operator \( \frac{1}{\Delta x^4} D^2_x \), where

\[
A \psi_{\text{real}}^n(k) = \frac{1}{\Delta \lambda} \psi_{\text{real}}^n(k+1) - 2 \psi_{\text{real}}^n(k) + \psi_{\text{real}}^n(k-1),
\]

(19a)

with \( O(\Delta \lambda^2) \),

\[
A \psi_{\text{real}}^n(k) = \frac{1}{12 \Delta \lambda^2} \left[ -\psi_{\text{real}}^n(k+2) + 16 \psi_{\text{real}}^n(k+1) - 30 \psi_{\text{real}}^n(k) + 16 \psi_{\text{real}}^n(k-1) - \psi_{\text{real}}^n(k-2) \right],
\]

(19b)

with \( O(\Delta \lambda^4) \),

and similar finite difference approximations for \( A \psi_{\text{imag}}^{n+1/2}(k) \). We assume that \( V \) is a constant and use the Von Neumann analysis [34] to analyze the stability of the generalized FDTD schemes. To this end, we first let \( \psi_{\text{real}}^n(k) = \lambda_{\text{real}}^n e^{\lambda_{\text{real}} \Delta \lambda} \) and \( \psi_{\text{imag}}^{n+1/2}(k) = \lambda_{\text{imag}}^n e^{\lambda_{\text{imag}} \Delta \lambda} \), where \( \lambda_{\text{real}}^n \) and \( \lambda_{\text{imag}}^n \) are amplification factors for \( \psi_{\text{real}}^n(k) \) and \( \psi_{\text{imag}}^{n+1/2}(k) \), respectively, and substitute them into Equation (19a). This gives

\[
\frac{1}{\Delta \lambda^2} D^2_x \psi_{\text{real}}^n(k) = \frac{1}{\Delta \lambda^2} \left( -4 \sin^2 \frac{\beta \Delta \lambda}{2} \right) \lambda_{\text{real}}^n e^{\lambda_{\text{real}} \Delta \lambda},
\]

(20a)

\[
\frac{1}{\Delta \lambda^4} D^4_x \psi_{\text{imag}}^{n+1/2}(k) = \frac{1}{\Delta \lambda^4} \left( -4 \sin^2 \frac{\beta \Delta \lambda}{2} \right) \lambda_{\text{imag}}^n e^{\lambda_{\text{imag}} \Delta \lambda}.
\]

(20b)

Replacing \( A \) with \( \frac{1}{\Delta \lambda^2} \delta^2_x \) in Equation (18), substituting Equation (20) into the resulting equations, and then deleting the common factor \( e^{\lambda_{\text{imag}} \Delta \lambda} \), we obtain

\[
\lambda_{\text{real}}^n = \lambda_{\text{real}}^{n+1} + \sum_{p=0}^{N} \left( \frac{h}{2m} A - \frac{V}{h} \right)^{2p+1} \lambda_{\text{real}}^{n-1},
\]

(21a)
\[ \lambda_{\text{imag}}^n = \lambda_{\text{imag}}^{n+1} + 2 \sum_{p=0}^{N-1} \left( \frac{-1}{(2p+1)!} \left( \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} + V \Delta t \right) \right)^{2p+1} \lambda_{\text{real}}^{n+1}, \]

(21b)

where \( r = \frac{\Delta t}{\Delta x^2} \). Since Equation (21a) is true for any time level \( n \), we rewrite Equation (21a) as

\[ \lambda_{\text{real}}^{n+1} = \lambda_{\text{real}}^n + 2 \sum_{p=0}^{N-1} \left( \frac{-1}{(2p+1)!} \left( \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} + V \Delta t \right) \right)^{2p+1} \lambda_{\text{imag}}^n, \]

(22)

subtract it by Equation (21a), and then use Equation (21b) to eliminate \( \lambda_{\text{imag}}^n \). As such, we obtain a quadratic equation for \( \lambda_{\text{real}} \) as follows:

\[ \lambda_{\text{real}}^2 - 2 - \alpha^2 = 0, \]

(23)

where \( \alpha = 2 \sum_{p=0}^{N} \left( \frac{-1}{(2p+1)!} \left( \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} + V \Delta t \right) \right)^{2p+1} \). Using the fact that for a quadratic equation \( x^2 + Bx + C = 0 \) the solution \( x \) satisfies \( |x| \leq 1 \) if and only if \( |B| \leq |C| \) and \( |C| \leq 1 \) we obtain from Equation (23) that \( |\lambda_{\text{real}}| \leq 1 \) if and only if \( |\alpha| \leq 2 \). By the Von Neumann analysis, we conclude that the generalized FDTD scheme is stable if \( |\alpha| \leq 2 \), i.e.,

\[ \left| \sum_{p=0}^{N} \left( \frac{-1}{(2p+1)!} \left( \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} + V \Delta t \right) \right)^{2p+1} \right| \leq 1. \]

(24)

It can be seen that

\[ \lim_{N \to \infty} \sum_{p=0}^{N} \left( \frac{-1}{(2p+1)!} \left( \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} + V \Delta t \right) \right)^{2p+1} = \sum_{p=0}^{N} \left( \frac{-1}{(2p+1)!} \left( \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} + V \Delta t \right) \right)^{2p+1} \]

\[ = \sin \left( \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} + V \Delta t \right), \]

implying that, when \( N \to \infty \), Equation (24) is automatically satisfied, and, hence, the scheme with \( N \to \infty \), is unconditionally stable. However, we cannot choose \( N = \infty \) and, therefore, the generalized FDTD scheme should be imposed the condition in Equation (24). Noting that the condition in Equation (24) gives only \( |\lambda_{\text{real}}| \leq 1 \) and does not indicate whether or not there is a double root with \( |\lambda_{\text{real}}| = 1 \) in Equation (23) (for this case, the numerical solution may still blow up), we choose the maximum value of \( \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} \) and require

\[ \sum_{p=0}^{N} \left( \frac{-1}{(2p+1)!} \left( \frac{m}{r} + V \Delta t \right) \right)^{2p+1} \leq c < 1, \]

(26)

where \( c \) is a constant. Using a similar argument, we may obtain the same inequality as that in Equation (26) for \( \lambda_{\text{imag}} \). Hence, we obtain the following theorem.

**Theorem 1.** The generalized FDTD scheme

\[ \psi_{\text{real}}^n(k) = \psi_{\text{imag}}^{n+1}(k) \]

\[ + 2 \sum_{p=0}^{N} \left( \frac{-1}{(2p+1)!} \left( \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} + V \Delta t \right) \right)^{2p+1} \psi_{\text{imag}}^n(k), \]

(27a)

\[ \psi_{\text{imag}}^{n+1}(k) = \psi_{\text{imag}}^{n+1}(k) \]

\[ + 2 \sum_{p=0}^{N} \left( \frac{-1}{(2p+1)!} \left( \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} + V \Delta t \right) \right)^{2p+1} \psi_{\text{real}}^n(k). \]

(27b)

is stable if Equation (26) is satisfied.

It can be seen that when \( N = 0 \) the condition in Equation (26) reduces to that in Equation (9). Also, the accuracy of the scheme is \( O(\Delta x^2 + \Delta \Delta \Delta t^2 + \cdots + \Delta \Delta \Delta \Delta \Delta \Delta t^2 \).

Similarly, for the fourth-order central difference \( \frac{1}{\Delta x^4} D_{x}^4 \) case, we let \( \lambda_{\text{real}}(k) = \lambda_{\text{real}}^{\alpha \beta / \beta \alpha} \) and

\[ \psi_{\text{imag}}^{n+1}(k) = \lambda_{\text{imag}}^{\alpha \beta / \beta \alpha}, \]

and substitute them into Equation (19b). This gives

\[ \frac{1}{\Delta x^4} D_{x}^4 \psi_{\text{real}}(k) \]

\[ = - \frac{4}{\Delta x^2} \sin^2 \frac{\beta \Delta x}{2} \left( 3 + 4 \sin^2 \frac{\beta \Delta x}{2} \right) \lambda_{\text{real}}^{\alpha \beta / \beta \alpha}, \]

(28a)

\[ \frac{1}{\Delta x^4} D_{x}^4 \psi_{\text{imag}}(k) \]

\[ = - \frac{4}{\Delta x^2} \sin^2 \frac{\beta \Delta x}{2} \left( 3 + 4 \sin^2 \frac{\beta \Delta x}{2} \right) \lambda_{\text{imag}}^{\alpha \beta / \beta \alpha}. \]

(28b)

Replacing \( A \) with \( \frac{1}{\Delta x^4} D_{x}^4 \) substituting Equation (28) into Equation (18), and deleting the common factor \( e^{\alpha \beta / \beta \alpha} \), we obtain a quadratic equation for \( \lambda_{\text{real}} \) as follows:

\[ \lambda_{\text{real}}^2 - 2 - \alpha^2 = 0, \]

(29)

where

\[ \alpha = 2 \sum_{p=0}^{N} \left( \frac{-1}{(2p+1)!} \left( \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} + V \Delta t \right) \right)^{2p+1} \]

\[ \left[ \frac{m}{r} \sin \beta \Delta x \frac{\beta \Delta t}{2} + V \Delta t \right]. \]

Hence, we use a similar argument as before and obtain the following theorem.

**Theorem 2.** The generalized FDTD scheme
\[ 
\psi^{n+1}_\text{real}(k) = \psi^{n+1}_\text{real}(k) 
+ 2 \sum_{p=1}^{N-1} \frac{(-1)^{p+1}}{2(p+1)!} \left( \frac{h}{4m rD^2_s} - \frac{V \Delta t}{2h} \right)^{2p+1} \psi^{n+1/2}_\text{imag}(k), \]

(30a)

\[ 
\psi^{n+1/2}_\text{imag}(k) = \psi^{n+1/2}_\text{imag}(k) 
+ 2 \sum_{p=1}^{N-1} \frac{(-1)^{p}}{2(p+1)!} \left( \frac{h}{4m rD^2_s} - \frac{V \Delta t}{2h} \right)^{2p+1} \psi^{n}_\text{real}(k). \]

(30b)

is stable if the following condition is satisfied

\[ 
\sum_{p=1}^{N-1} \frac{(-1)^{p}}{2(p+1)!} \left( \frac{4h}{3m} + \frac{V \Delta t}{2h} \right)^{2p+1} \leq c < 1, \]

(31)

where \( c \) is a constant.

The accuracy of the scheme is \( O(\Delta x^2 + \Delta T^2 \Delta x^2 + \ldots + \Delta x^{2N+2}) \). It can be seen from the above both schemes for that larger \( N \), the evaluation for powers of \( b_i^2 \) or \( D_i^2 \) can be very expensive. Therefore, it is our suggestion to choose a smaller \( N \) for computation.

### 4. Absorbing Boundary Condition

When the particle travels and hits the boundary, it will distort the wave packet solution. It is ideal to create an absorbing boundary condition so that the particle will not reflect back to the domain under consideration. This will distort the wave packet solution. We develop a second-order absorbing boundary condition (ABC) which is obtained from analyzing the group velocity of the wave packet at the boundaries [15]. To this end, we assume group velocities of the traveling particle to be

\[ 
v_i = \frac{h k_j}{m} = \frac{2\pi}{\lambda_j}, \quad v_2 = \frac{h k_j}{m} = \frac{2\pi}{\lambda_j}, \]

where \( k_j = \frac{2\pi}{\lambda_j}, \: j = 1,2 \), is the wavenumber and \( \lambda_j \) is the wavelength. By incorporating the dispersion relation \( \frac{h^2 k_j^2}{2m} = 2\pi v/h - V \) derived from Equation (1), one may see that the wavenumber \( k_j = \frac{2\pi}{\lambda_j} \) corresponds to \( -i \partial_x \).

Thus, the differential form of the wavenumber can be obtained as

\[ 
\left( i \partial_x + \frac{mv_i}{h} \right) \psi(x,t) = 0. \]

(33)

Since a wave maintains various components with different group velocities, we impose a higher-order boundary condition as follows:

\[ 
\left( i \partial_x + \frac{mv_i}{h} \right) \psi(x,t) = 0. \]

(34)

It should be pointed out that for a wave traveling towards the left, \( v_i \) and \( v_2 \) are substituted by \( -v_i \) and \( -v_2 \). It may be seen from Equations (33) and (34) that if \( v_i \) does not equal \( v_2 \), the two different wave components with group velocities \( v_i \) and \( v_2 \) will be absorbed, and on the other hand, if \( v_i \) is equal to \( v_2 \) the component of the wave with group velocity \( v_i \) (or \( v_2 \)) will be absorbed to the second order.

With Equations (5), (6) and (34), the wavefunctions at the left and right boundaries can be determined as

\[ 
\pm h \partial_x \psi^{\text{real}}(x,t) - c_1 h \partial_x \psi^{\text{imag}}(x,t) = 0, \]

(35a)

\[ 
\mp h \partial_x \psi^{\text{imag}}(x,t) + c_2 h \partial_x \psi^{\text{real}}(x,t) = 0, \]

(35b)

where

\[ 
c_1 = \frac{2}{(v_1 + v_2)}, \quad c_2 = \frac{mv_i v_2}{(v_1 + v_2)}. \]

(36)

Here, the upper signs in Equation (35) apply to the left boundary, whereas the lower signs apply to the right. We then use the second-order finite difference schemes to approximate \( \psi^{\text{real}} \) and \( \psi^{\text{imag}} \) at the left \( (k = 1) \) and right \( (k = N - 1) \) boundaries as follows, respectively,

\[ 
\psi^{\text{imag}}(x_k, t_n+1/2) \approx \psi^{n+1/2}_\text{imag}(k) + \psi^{n+1/2}_\text{imag}(k+1) / 2, \]

(37a)

\[ 
\partial_x \psi^{\text{imag}}(x_k, t_n+1/2) \approx \psi^{n+1/2}_\text{imag}(k+1) - \psi^{n+1/2}_\text{imag}(k) / \Delta x, \]

(37b)

\[ 
\partial_x \psi^{\text{real}}(x_k, t_n+1/2) \approx \psi^{n+1/2}_\text{real}(k) - \psi^{n+1/2}_\text{real}(k) / \Delta t, \]

(37c)

and

\[ 
\psi^{\text{real}}(x_k, t_n) \approx \psi^{\text{real}}(k) + \psi^{\text{real}}(k+1) / 2, \]

(38a)

\[ 
\partial_x \psi^{\text{real}}(x_k, t_n) \approx \psi^{\text{real}}(k+1) - \psi^{\text{real}}(k) / \Delta x, \]

(38b)

\[ 
\partial_t \psi^{\text{real}}(x_k, t_n) \approx \psi^{\text{real}}(k) - \psi^{\text{real}}(k) / \Delta t. \]

(38c)

Upon substituting Equations (37) and (38) into Equation (35), we obtain discrete absorbing boundary conditions as follows:

\[ 
-\psi^{n+1/2}_\text{imag}(k) \left( \frac{\pm 1}{\Delta x} + c_1 \right) \psi^{\text{real}}(k+1) + \frac{c_2 \psi^{n+1}_\text{real}(k)}{\Delta t} \]

\[ 
= -\psi^{n+1/2}_\text{imag}(k) \psi^{n+1/2}_\text{imag}(k+1) + \frac{c_2 \psi^{n+1/2}_\text{real}(k+1)}{2h(c_1 V - c_2)^2}, \]

(39a)
and
\[ -\psi^{n+1}_{\text{real}}(k) \left( \frac{\Delta t}{\Delta x} - \frac{c_i}{\Delta t} \right) + \frac{c_i \psi^{n+1/2}_{\text{imag}}(k + 1) - c_i \psi^{n-1/2}_{\text{imag}}(k)}{\Delta t} \]
\[ = \frac{\psi^{n}_{\text{real}}(k) + \psi^{n}_{\text{real}}(k + 1)}{2h(c_i V - c_j)^{-1}}. \]  

(39b)

5. Numerical Examples

To test the stability of the generalized FDTD schemes in Equation (27) and Equation (30) with discrete absorbing boundary conditions, Equation (39), we employed the present schemes and the original FDTD scheme to simulate a particle moving in free space and then hitting an energy potential as tested in [3]. To this end, we initiated a particle at a wavelength of \( \lambda \) in a Gaussian envelop of width \( \sigma \) with the following two equations:

\[ \psi^0_{\text{real}}(k) = e^{-\frac{1}{2} \left( \frac{k-k_0}{\sigma} \right)^2} \cos \left( \frac{2\pi (k-k_0)}{\lambda} \right) \]  

(40a)

and

\[ \psi^0_{\text{imag}}(k) = e^{-\frac{1}{2} \left( \frac{k-k_0}{\sigma} \right)^2} \sin \left( \frac{2\pi (k-k_0)}{\lambda} \right), \]  

(40b)

where \( k_0 \) is the center of the pulse. We chose a mesh of 1600 spatial grid points and the following values for parameters [3]: \( h = 1.054 \times 10^{-14} \text{ J-sec} \), \( m = 9.1 \times 10^{-31} \text{ kg} \), \( \Delta x = 0.1 \times 10^{-10} \text{ m} \), \( k_0 = 400 \), and \( \sigma = \lambda = 0.1 \times 10^{-10} \text{ m} \). Furthermore, \( V \) was chosen to be 0 in the first 800 grid points and 100 eV in the next 800 grid points.

Two quantities of importance in quantum mechanics are the expected values of the kinetic energy and the potential energy. They are calculated from \( \psi_{\text{real}}^n(k) \) and \( \psi_{\text{imag}}^{n+1/2}(k) \) in the simulation as follows,

Kinetic Energy (KE)

\[ = -\frac{\hbar^2}{2m} \sum_{k=1}^{N} \left[ 2 \psi_{\text{real}}^n(k) - i \psi_{\text{imag}}^{n+1/2}(k) \right] \]  

(41b)

\[ + \frac{\partial^2 \psi_{\text{real}}^n(k)}{\partial x^2} + i \frac{\partial^2 \psi_{\text{imag}}^{n+1/2}(k)}{\partial x^2} \],

and

Potential Energy (PE)

\[ = \sum_{k=1}^{N} V(k) \left[ |\psi_{\text{real}}^n(k)|^2 + |\psi_{\text{imag}}^{n+1/2}(k)|^2 \right], \]  

(41b)

where \( \frac{\partial^2 \psi_{\text{real}}^n(k)}{\partial x^2} \) and \( \frac{\partial^2 \psi_{\text{imag}}^{n+1/2}(k)}{\partial x^2} \) are evaluated using the fourth-order finite difference approximations:

\[ \frac{\partial^2 \psi_{\text{real}}^n(k)}{\partial x^2} \approx \frac{1}{12\Delta x^2} \left[ -\psi_{\text{real}}^n(k) + 16\psi_{\text{real}}^n(k + 1) - 30\psi_{\text{real}}^n(k + 2) + 16\psi_{\text{real}}^n(k + 3) - \psi_{\text{real}}^n(k + 4) \right], \]  

(42a)

and

\[ \frac{\partial^2 \psi_{\text{imag}}^{n+1/2}(k)}{\partial x^2} \approx \frac{1}{12\Delta x^2} \left[ -\psi_{\text{imag}}^{n+1/2}(k) + 16\psi_{\text{imag}}^{n+1/2}(k + 1) - 30\psi_{\text{imag}}^{n+1/2}(k + 2) + 16\psi_{\text{imag}}^{n+1/2}(k + 3) - \psi_{\text{imag}}^{n+1/2}(k + 4) \right]. \]  

(42b)

Based on the above formula, the electron moves in free space and then hits an energy potential with a total energy of about 150 eV. The energy is purely kinetic due to the fact that there is no potential energy available before the energy barrier is reached. With an increase in time, the electron will propagate in the positive spatial direction. The waveform begins to spread, but the total kinetic energy remains constant. After the electron strikes the potential barrier, part of the energy will be converted to potential energy. The waveform indicates that there is some probability that the electron is reflected and some probability that it penetrates the potential barrier. However, the total energy should remain constant.

In our computations, we chose \( N = 2 \) in Equation (27) and Equation (30), and let

\[ \Delta t = \frac{2m\Delta x^2}{\hbar}, \]  

(43)

where \( \mu \) is a parameter used in [3]. Using Equation (43), we rewrite the conditions in Equation (26) and Equation (31) for \( N = 2 \) as

\[ \left| \sum_{p=1}^{N/2} \left( \frac{8}{3} \mu + \frac{\max |V| \Delta t}{2h} \right)^{2p+1} \right| \leq c < 1, \]  

(44a)

\[ \left| \sum_{p=1}^{N/2} \left( \frac{8}{3} \mu + \frac{\max |V| \Delta t}{2h} \right)^{2p+1} \right| \leq c < 1. \]  

(44b)

Figures 1 and 2 show the simulation of an electron moving in free space and then hitting a potential of 100 eV, which was obtained by using the original FDTD-Q scheme (\( N = 0 \)) with \( \mu = 0.46875 \). It can be seen that when \( \mu = 0.46875 \) (in which \( \frac{\hbar^2}{m} + \frac{\max |V| \Delta t}{2h} = 2\mu + \frac{\Delta t}{2h} \cdot \max |V| \leq 0.9375 + 1.7 \times 10^{-26} < 1 \), the FDTD-Q scheme is stable and indeed the numerical solution does not diverge. Figure 1 shows that when the absorbing boundary condition is not imposed, the wavepacket is distorted at \( n = 5 \times 10^4 \). On the other hand, Figure 2 shows that when the absorbing boundary condition is imposed. Similar results
are obtained when we used the generalized FDTD scheme ($N = 2$) with $\mu = 0.46875$.

It is noted that when $\mu = 0.5$ the original FDTD-Q scheme produces a divergent solution, because
\[
\frac{\hbar}{m} r + \frac{\Delta t}{2\hbar} \max |V| = 2\mu + \frac{\Delta t}{2\hbar} \max |V| > 1
\]
which violates the stability condition. Thus, we employed the generalized FDTD scheme, Equation (27) with $N = 2$ and Equation (30) with $N = 2$ for this case. It is noted that when $\mu = 0.5$,
\[
\sum_{p=0}^{3} \left( \frac{-1}{2p+1} \right) \left( 2\mu \frac{\max |V| \Delta t}{2\hbar} \right)^{2p+1} 
\leq 0.8418 + 1.7 \times 10^{-26} < 1,
\]
implying the stability condition Equation (26) is satisfied, and
\[
\sum_{p=0}^{3} \left( \frac{-1}{2p+1} \right) \left( \frac{8}{3} \mu \frac{\max |V| \Delta t}{2\hbar} \right)^{2p+1} 
\leq 0.9735 + 1.7 \times 10^{-26} < 1
\]
implying the stability condition Equation (31) is satisfied.

Figures 3 and 4 show the simulation of an electron moving in free space and then hitting a potential of 100 eV, which was obtained using the generalized FDTD scheme,
Equation (27) with \( N = 2 \) and \( \mu = 0.5 \). It can be seen from Figure 3 that when the absorbing boundary condition is not imposed, the wavepacket is distorted at \( n = 5.0 \times 10^3 \). On the other hand, when an absorbing boundary condition is imposed, the wavepacket disappears at \( n = 5.0 \times 10^4 \) as shown in Figure 4.

Figures 5 and 6 show the simulation of an electron moving in free space and then hitting a potential at \( n = 5.0 \times 10^4 \). On the other hand, when an absorbing boundary condition is imposed, the wavepacket disappears as shown in Figure 6.

The above numerical example indicates that both generalized FDTD schemes break through the limitation (\( \mu < 0.5 \)) of the original FDTD-Q scheme. It should be pointed out that one may obtain a larger value of \( \mu \) if \( N \) is chosen to be larger in the generalized FDTD scheme.

6. Conclusion

We have developed a generalized FDTD method with absorbing boundary condition for solving the 1D time-dependent Schrödinger equation and obtain a more relaxed condition for stability when central difference

Figure 4. Simulation of an electron moving in free space and then hitting a potential. The second-order FDTD scheme was employed with \( \mu = 0.5 \) and absorbing boundary condition.

Figure 5. Simulation of an electron moving in free space and then hitting a potential. The fourth-order FDTD scheme was employed with \( \mu = 0.5 \) and no absorbing boundary condition.

Figure 6. Simulation of an electron moving in free space and then hitting a potential. The fourth-order FDTD scheme was employed with \( \mu = 0.5 \) and absorbing boundary condition.
approximations are employed for spatial derivatives. Numerical results coincide with those obtained based on the theoretical analysis.
